

GPU-Accelerated 3D Ant Colony Simulation and Visualization

Dan Andersen

Motivation / Background

- ▶ Ant colony optimization algorithms are useful for pathfinding
 - ▶ Robotics, distributed networks
- ▶ Each ant only needs knowledge of its immediate surroundings
 - ▶ This makes it great for parallelization / GPGPU
- ▶ Basic setup:
 - ▶ Ants wander randomly from nest, laying pheromone trails
 - ▶ They pick up food and bring it back to the nest
 - ▶ Other ants follow the trail to the food

Demo

Approach - Simulation - World

- ▶ 3D texture ($N \times N \times N$)
 - ▶ Red: Nest
 - ▶ Green: Food Amount
 - ▶ Blue: Trail Strength
 - ▶ Alpha: Ant
- ▶ Shader sets trail to max value if ant is in cell
 - ▶ Otherwise, fades the trail

Approach - Simulation - Ant

- ▶ 2D texture ($M \times 1$)
 - ▶ RGB: XYZ position in world
 - ▶ Alpha: ant state (direction, carrying food)
- ▶ For each ant, the fragment shader:
 - ▶ Picks up / drops off food
 - ▶ Determines where the ant is allowed to move
 - ▶ Calculates score for each possible choice
 - ▶ Moves to best choice (sometimes moves randomly)

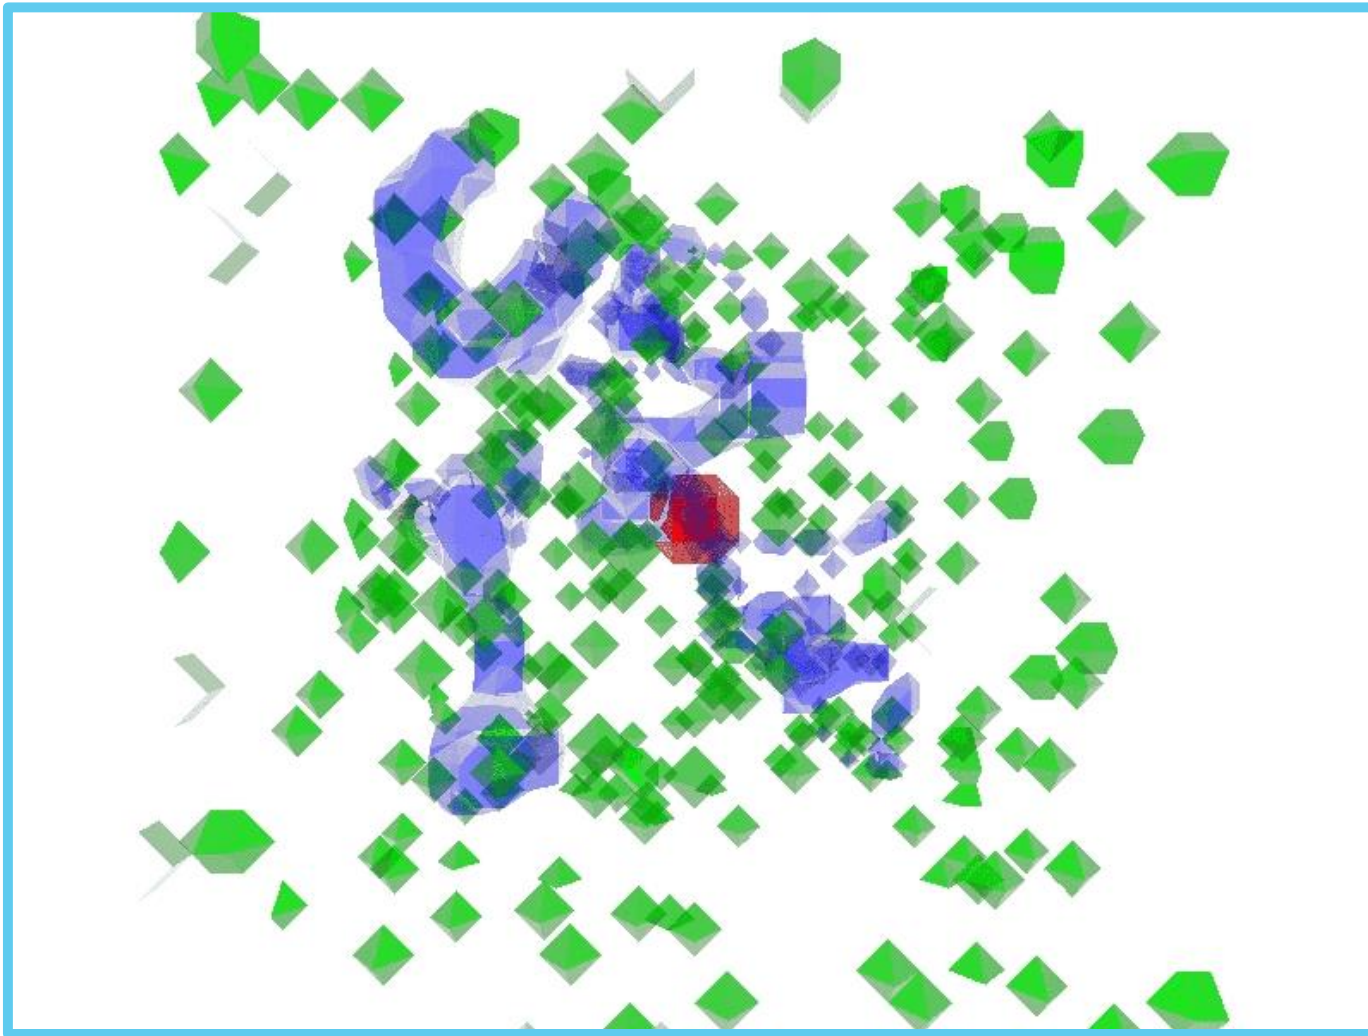

Approach - Visualization

- ▶ Geometry shader
 - ▶ Input: a single vertex at each grid point
 - ▶ Output: A set of triangles for the mesh near that point
- ▶ Using marching cubes algorithm (Lorensen 1987)
 - ▶ Evaluate value at point and 8 surrounding points
 - ▶ Look up in array of 256 possible configurations
 - ▶ Use linear interpolation to determine vertex locations

Demo

Results

- ▶ Swarm behavior of ants is sensitive to variation in ant path-finding algorithm
 - ▶ Ants can get stuck in their own trail
 - ▶ This happens in the real world too (ant mills)
- ▶ Runs at real-time rates up to world size of 128x128x128

Summary

- ▶ Simulated ant-like motion using fragment shaders
- ▶ Visualized simulation using marching cube algorithm in geometry shaders
- ▶ UI includes customizable parameters

Future Work

- ▶ Use of VBOs can improve visualization performance
- ▶ Different trails (toward food and toward nest) can improve swarm behavior
- ▶ Storing history of ant movement can prevent self-loops
- ▶ Weighted random selection of possible destinations, rather than always choosing highest score
